Index, 249
Paediatrics is a rapidly evolving field of medicine, particularly in the sub-specialties. This makes it difficult for trainees, junior doctors and allied health professionals to keep up with new developments.

This book aims to provide problem-orientated clinical scenarios in paediatric gastroenterology, hepatology and nutrition, and is designed to make initial assessment, management and referral of children easy to follow.

The book is up to date with current practice, user friendly, with links to the latest guidance, protocols and information, and should be a popular book no trainee doctor should be without.

We hope you enjoy using it and that it will help you improve how you manage children with these specialist conditions.
Dr Indra van Mourik, Consultant Hepatologist, The Liver Unit, Birmingham Children’s Hospital, Birmingham, UK

Sara Clark, Senior Dietitian, The Liver Unit, Birmingham Children’s Hospital, Birmingham, UK

Simon Fraser, Nutrition Pharmacist, Royal Hospital for Sick Children, Glasgow, UK

Avril Smith, Gastrostomy Nurse Specialist, Royal Hospital for Sick Children, Glasgow, UK

Guftar Sheikh, Consultant Endocrinologist, Royal Hospital for Sick Children, Glasgow, UK
Abdominal symptoms are often non-specific, with a wide differential diagnosis. We aim to provide a framework for evaluation, with information for both common and important rare conditions. A multidisciplinary model of care supports optimal management and outcomes. Specialist nursing, dietetics and psychology are central to supporting therapy, especially in chronic illness. Specialist advice and management for rare or complex problems are important, as is recognising non-gastrointestinal illness and conditions requiring surgical intervention, often provided through a defined network of units with pathways for referral, and shared-care with community and hospital teams.
It can be difficult to distinguish between ‘normal’ colic and pathological conditions.

Infantile colic is common in the first months of life. Babies scream, draw up their knees and experience severe pain. Episodes may last up to 3 hours and occur several times per week. Causes are listed in Table 1.1.

Pathological pain from any site may be interpreted as abdominal in origin, e.g. corneal abrasion, renal tract obstruction, bony fracture.

Investigations

Normal results from screening blood tests can help reassure that underlying renal, liver or metabolic diseases are unlikely.

- FBC, renal, liver and bone biochemistry, blood gases
- Urine analysis and culture
- Plain abdominal radiograph: volvulus in the ill child or with bilious vomiting
- Abdominal ultrasound scan: when intussusception suspected
- Barium swallow and follow to the duodenal–jejunal flexure: to exclude malrotation
- Endoscopy is rarely indicated

Management

In the absence of other obvious cause, a time-limited trial of hypoallergenic feed can be useful to exclude milk allergy/intolerance (see Chapter 12), and antacid therapy can be used if there is acid reflux-related oesophagitis. Most often, colic settles within a few weeks or with changes in routine.
Table 1.1 Causes, cardinal signs and diagnostic investigations in a child with abdominal pain

MCADD, medium-chain acyl-CoA dehydrogenase deficiency.

### Red flags: When colic is concerning

- **Abdominal distension** (see Chapter 6)
- **Faltering growth**: feeding problem (see Chapters 37, 38 and 39) or malabsorption (see Chapter 9)
- **Abnormal developmental progress**: severe oesophagitis more likely, underlying metabolic disorder
Abdominal pain is common in school-aged children and is rarely organic.

**History**

- Duration and location [right upper quadrant pain in hepatitis, Gilbert’s syndrome and non-alcoholic steatohepatitis (NASH)]
- Associated symptoms: vomiting, dyspepsia, diarrhoea, fever, groin pain, urinary symptoms
- Blood in stool
- Vaginal discharge
- Foreign travel
- Gynaecological and sexual history
- Family history: inflammatory bowel disease, coeliac disease, migraine, irritable bowel syndrome, gallstones, pancreatitis

**Investigations**

- Urinalysis: haematuria in renal stones, pyuria in urinary tract infection
- Urine microscopy, culture, sensitivities
- Blood tests: blood glucose, FBC, renal function, liver function, inflammatory markers, amylase, cholesterol, triglycerides
- Other blood tests if indicated, e.g. paracetamol levels, thyroid function tests
- Stool samples if diarrhoea: microscopy, culture, sensitivity, ova, cysts, parasites
The child with abdominal pain

- Abdominal imaging:
  - Abdominal X-ray, e.g. if looking for obstruction
  - Chest X-ray, e.g. for pneumonia or air under the diaphragm
  - Ultrasound scan of the abdomen, kidneys, pelvis (females) and testes (males)
  - CT scan may also be appropriate, especially if there is a mass, trauma, jaundice or pancreatitis
- Endoscopy: will depend upon preliminary findings and history; in the absence of any abnormality on blood screen and imaging, negative endoscopy is very likely

Causes

Well child
- Functional bowel disease: recurrent abdominal pain of childhood, abdominal migraine
- Lactose intolerance: worse with dairy products (ice cream and chocolate are high lactose)
- Gastro-oesophageal reflux ± oesophagitis: dyspepsia, epigastric pain, regurgitation
- Constipation: hard, infrequent stools, soiling
- Renal pelvic/ureteric obstruction: intermittent colicky loin pain
- Coeliac disease: variable association with iron deficiency, diarrhoea, oral aphthous ulceration
- Food allergy (see Chapter 12)
- NASH: associated with obesity and metabolic syndrome

Febrile child
- Gastroenteritis (bacterial or viral)
- Mesenteric adenitis
- Urinary tract infection (lower abdominal pain, loin pain – suggests pyleonephritis)
- Pneumonia
- Inflammatory bowel disease
- Liver abscess

The ill child
- Diabetic ketoacidosis: check urine for glucose, blood gases
- Mesenteric lymphadenitis: fever, often with associated tonsillitis or pharyngitis
- Peptic ulcer disease: sharp epigastric pain after meals
- Hepatitis: raised liver transaminases ± jaundice; see Chapter 21
- Pancreatitis: high amylase, bilirubin and transaminases may be raised
- Ultrasound: biliary dilatation may be seen in acute pancreatitis
- DNA: PRSS1 mutations in familial pancreatitis, raised serum amylase and lipase
- Sickle cell anaemia/crisis: blood film shows sickle cells
- Henoch–Schönlein purpura: characteristic vasculitic rash, haematuria or proteinuria
- Acute adrenal failure: hyponatraemia ± hyperkalaemia, check for inappropriate urinary sodium losses

**Surgical causes**
- Appendicitis: low-grade fever, central then right iliac fossa pain, unable to stand (psoas irritation), beware of atypical symptoms
- Bowel obstruction, e.g. intussusception, volvulus: bilious vomiting, abdominal distension, tenderness
- Trauma, e.g. haematoma, pancreatitis, liver trauma: may present several days after the event. Low haemoglobin, CT scan will identify liver laceration/pancreatic transection or liver abscesses
- Incarcerated hernia: groin or scrotal swelling/discolouration/pain
- Peritonitis: rigid abdomen or distension with tenderness
- Liver abscess: ultrasound – abscess(es) in liver, raised white cell count, blood culture or aspirate from the abscess may grow pathogen (most commonly *Streptococcus* or *Klebsiella*)
- Gallstones/cholecystitis: sickle cell on blood film, raised bilirubin if obstruction, abnormal transaminases, high amylase if the ampulla of Vater is affected, cholesterol or triglycerides may be high, ultrasound – acoustic shadow (Figure 2.1), biliary dilatation if the gallstone is causing obstruction
- Testicular torsion: scrotal swelling, tenderness, discolouration
- Ureteric calculi: colicky pain, macro- or micro-scopic haematuria

**Gynaecological causes**
- Dysmenorrhoea or endometriosis: prior and/or during menstrual bleed
- Mittelschmerz: mid-cycle colicky pain
- Pelvic inflammatory disease: fever variable

**Obstetric causes**
- Ectopic pregnancy: sudden onset with shock or peritonism
- Ovarian cyst rupture/torsion
- Miscarriage/abortion/retained foetal products
The child with abdominal pain

Drugs/toxins
- Paracetamol overdose
- Iron overdose
- Venoms: spider bite, scorpion sting
- Soap ingestion
- Erythromycin

Referred pain
- Usually musculoskeletal: examine for scoliosis, joint tenderness

Rare causes
- Angioneurotic oedema: episodic, rash or facial/lip swelling – allergy/immunology referral
- Familial Mediterranean fever or systemic lupus erythematosis: episodic fever and raised inflammatory markers with extra-intestinal symptoms – rheumatology referral
- Acute intermittent porphyria: episodic, send urine for porphyrins during an attack
- Peptic ulcer disease – often associated with *Helicobacter pylori* infection

Figure 2.1 Ultrasound scan appearance of gallstones with acoustic shadows. The gallbladder wall (marked with crosses) is irregular and thick, consistent with chronic cholecystitis.
### Information: Rome III criteria for functional bowel diseases

- No evidence of an inflammatory, anatomical, metabolic or neoplastic process
- Symptoms: at least once a week for at least 2 months before diagnosis

**Functional dyspepsia**
- Persistent or recurrent pain or discomfort above the umbilicus
- Not relieved by defecation or associated with the onset of a change in stool frequency or stool form

**Irritable bowel syndrome**
Abdominal discomfort or pain associated with two or more of the following at least 25% of the time:
- Improved with defecation
- Onset associated with a change in frequency of stool
- Onset associated with a change in form (appearance) of stool

**Functional abdominal pain**
- Episodic or continuous abdominal pain
- Insufficient criteria for other functional gastrointestinal disorders

**Functional abdominal pain syndrome**
- Must include: functional abdominal pain at least 25% of the time and either some loss of daily functioning or additional somatic symptoms such as headache, limb pain or difficulty in sleeping

### Information: Abdominal migraine

**Criteria:**
- Two or more times in the preceding 12 months
- Paroxysmal episodes of intense peri-umbilical pain lasting >1 hour
- Intervening periods of usual health lasting weeks to months
- Pain interferes with normal activities
- Pain is associated with two or more of the following:
  - Anorexia
  - Nausea
  - Vomiting
  - Headache
  - Photophobia
  - Pallor
Red flags: When to be concerned about abdominal pain

- Unintentional weight loss
- Growth failure or slowing
- Unexplained fever
- Chronic severe diarrhoea or significant vomiting
- Gastrointestinal bleeding
- Family history of inflammatory bowel disease
- Persistent chronic right iliac fossa or right upper quadrant pain
- Recurrent pancreatitis: consider hereditary pancreatitis or lipidaemia

Information: Gallstones

Associated with:
- Haemolysis
- Prematurity
- Cystic fibrosis
- Down’s syndrome
- Bone marrow and cardiac transplantation
- Childhood cancer
- Spinal surgery/injury
- Hepatobiliary trauma
- Selective IgA deficiency
- Dystrophia myotonica
- Chronic intestinal pseudo-obstruction
- Cholestatic liver disease (especially progressive familial intrahepatic cholestasis)
- Congenital anomalies
  - There is a bimodal incidence with initial peaks in infancy and adolescence; more common in females.

Presentation
- In infancy: poor feeding, vomiting and jaundice
- In older children: right upper quadrant or epigastric pain, nausea, vomiting and obstructive jaundice

Diagnosis
- Stones cast acoustic shadow on ultrasound and a thick-walled gallbladder (see Figure 2.1)

(Continued)
Management

Functional abdominal pain
- Reassurance that there is no evidence of organic pathology
- Significant persistent symptoms require multidisciplinary input with a family-based holistic approach

Medications
- Functional abdominal symptoms respond poorly to acid reduction therapy or antispasmodics
- Peppermint oil (one or two capsules three times daily) is most likely to be effective
- Mebeverine hydrochloride: 25mg three times daily (age 3–4 years); 50mg three times daily (age 4–8 years); 100mg three times daily (age 8–10 years); 135–150mg three times daily (age over 10 years)
- Dicycloverine hydrochloride: 5–10mg before feeds (age 6 months–2 years); 10–20mg three times daily (over age 2 years)
- Hyoscine butylbromide: 0.5mg/kg, max. 5mg three times daily (age 1 month–2 years); 5mg three times daily (2–5 years); 10–20mg three times daily (over 5 years)
- Abdominal migraine can be prevented or ameliorated by using a serotonin 2A receptor antagonist, pizotifen 0.25–0.5mg twice or three times daily

Dietary management
Food allergy and intolerance is common in small children, and dietary manipulation is often attempted by families prior to seeking advice from health professionals. In practice, this is rarely effective and puts children at risk of nutrient deficiency (e.g. dairy exclusion and suboptimal calcium intake).

A careful history will identify those with food allergy or intolerance (see Chapter 12). Lactose intolerance is common in Asian and Afro-Caribbean populations. There is little evidence that functional abdominal pain improves with a lactose-free diet in either lactase-deficient or -sufficient children.
Probiotics and prebiotics have not been shown to be effective, though do no harm.

**Psychological management**
Functional abdominal pain may stem from learned-behaviour responses to environmental and social stimuli that interact with the child’s experience of physical illness. This hypothesis is supported by psychological studies showing altered subliminal responsiveness to pain- and stress-related cues, and that maternal anxiety is a predictor. Psychological interventions, including family therapy, hypnotherapy and cognitive behavioural therapy, are effective in reducing the severity and duration of symptoms, and improving school attendance.

**Gallstones**
- Ursodeoxycholic acid 10–20 mg/kg/day with fat-soluble vitamins if there is obstructive jaundice
- Biliary dilatation requires removal of the stone by endoscopic manipulation through the ampulla of Vater using endoscopic retrograde cholangiopancreatography (ERCP)
- Laparoscopic cholecystectomy only when acute inflammation has resolved

**Liver abscess**
- Drainage of abscess
- Antibiotics (antifungals in immunosuppressed patients or if there is no response to antibiotics without culture sensitivities)

**Liver trauma**
- Resuscitation, pain relief, identify other injuries
- Conservative management unless haemorrhage is uncontrolled and then surgical intervention

**Further reading**

**Key web links**

http://79.170.44.126/britishlivertrust.org.uk/home-2/liver-information/liver-conditions/gallstones/

http://www.naspghan.org/user-assets/Documents/pdf/diseaseInfo/Pancreatitis-E.pdf

Around half of infants regurgitate, and this on its own is not significant. However, vomiting is the cardinal feature of many gastrointestinal, renal, metabolic or neurological diseases. Persistent, effortless vomiting or posseting are characteristic of gastro-oesophageal reflux, and this is associated with a wide range of conditions, adding to the difficulty in management.

### Important features from history

- **Acute onset:** infectious or surgical causes
- **Fever:** infection
- **Antenatal history:** maternal infection, antenatal ultrasound scan findings
- **Birth history:** prematurity, resuscitation
- **Assess frequency and feed volume,** characterise any feeding difficulties, effect of any changes in formulae
- **Weight loss:** systemic disease more likely
- **Oesophagitis symptoms,** e.g. irritability, back arching, feed refusal, haematemesis
- **Failure to growth:** no weight gain 2 weeks after birth or dropping through centiles
- **Neurological symptoms and developmental progress:** consider metabolic disease
- **Family history of bowel surgery:** malrotation, hiatus hernia, Hirschsprung’s disease
• Cough or frequent chest infections: recurrent aspiration, cystic fibrosis, tracheo-oesophageal fistula
• Stridor or apnoea: seek ENT review
• Eczema, diarrhoea, urticaria or family history of atopy: suggest possible food allergy

<table>
<thead>
<tr>
<th>Red flags: What to look for in a vomiting infant</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Exclude infection</td>
</tr>
<tr>
<td>• Always consider raised intracranial pressure: bulging fontanelle, climbing head circumference centiles</td>
</tr>
<tr>
<td>• Be alert to factitious or induced illness</td>
</tr>
</tbody>
</table>

**Causes**

**Neonate**

• Overfeeding: usual intake is 150–200 mL/kg/day
• Gastro-oesophageal reflux ± cow’s milk intolerance/allergy
• Bowel obstruction: duodenal web, small bowel atresia, volvulus, malrotation, Hirschsprung’s disease, imperforate anus
• Infection: gastroenteritis, septicaemia, urinary tract infection, pneumonia, meningitis
• Neonatal abstinence syndrome: opiate or amphetamine withdrawal
• Intracranial bleed or injury: bulging fontanelle
• Inborn error of metabolism, e.g. urea cycle disorder, fructosaemia
• Congenital adrenal hyperplasia: abnormal serum electrolytes
• H-type tracheo-oesophageal fistula: cough, recurrent aspiration
• Upper airway or ENT anomaly: apnoea, cough, choking

**Older infant**

• Overfeeding: usual intake is 120–150 mL/kg/day
• Gastro-oesophageal reflux
• Pyloric stenosis: blood gas for alkalosis, ultrasound scan, refer to surgeon for test feed
• Cow’s milk protein intolerance/allergy: trial of hypoallergenic feed, or maternal milk/soya restriction
• Infection: gastroenteritis, urinary tract, otitis media, pneumonia, meningitis, septicaemia
• Intracranial mass, bleed or head injury: consider CT scan
• Bowel obstruction: abdominal radiograph, refer to surgeon
• Testicular torsion: urgent referral to surgeon
- Intussusception: ultrasound scan, refer to surgeon, air enema reduction
- Ketoacidosis: blood sugar, blood gas for acidosis
- Appendicitis: fever and abdominal pain, ultrasound scan, refer to surgeon
- Cystinosis: hypophosphataemia, renal tubular leak

**Screening investigations** (see Algorithm 3.1)

- Blood pressure
- Urine dipstix: ketones, sugar
- Blood sugar
- Septic screen if febrile or unwell
- Blood gases ± metabolic disease screen: blood ammonia, serum amino acids, urine amino and organic acids
- Serum biochemistry: U&E, LFT, bone profile
- Abdominal radiograph if obstruction suspected
- Barium swallow and follow through to the duodenal–jejunal flexure to exclude malrotation

**Algorithm 3.1** Investigation of vomiting in infants
Reflux events are common in normal infants, and not always symptomatic. A barium meal is useful for malrotation or hiatus hernia, but not reflux. Oesophageal pH (impedance) probe studies (48–72 hours off antacids) confirm acid reflux, but often do not alter management. Acid detection greater than 10% of the time (the reflux index) indicates severe acid reflux, which is associated with oesophagitis. False-negative results are common, as are technical problems (misplaced or dislodged probe, inadequate symptom diary, non-acid reflux events). Impedance studies provide more information about non-acid events, but normative data are lacking.

### Table 3.1 Doses for antacids in gastro-oesophageal reflux

### Management of gastro-oesophageal reflux

#### Medication
- Thickeners, e.g. Carobel, Gaviscon infant
- Antacids: useful in oesophagitis (Table 3.1)
- Lower respiratory tract infections and gastroenteritis are more common in infants receiving proton pump inhibitors, e.g. omeprazole
- Prokinetics, e.g. domperidone, erythromycin, metoclopramide: often ineffective and associated with adverse events, though can be useful in difficult cases
